Abstract

Sentence Connectivity is a textual characteristic that may be incorporated intelligently for the selection of sentences of a well meaning summary. However, the existing summarization methods do not utilize its potential fully. The present paper introduces a novel method for single-document text summarization. It poses the text summarization task as an optimization problem, and attempts to solve it using Weighted Minimum Vertex Cover (wMVC), a graph-based algorithm. Textual entailment, an established indicator of semantic relationships between text units, is used to measure sentence connectivity and construct the graph on which wMVC operates. Experiments on a standard summarization dataset show that the suggested algorithm outperforms related methods.

1 Introduction

In the present age of digital revolution with proliferating numbers of internet-connected devices, we are facing an exponential rise in the volume of available information. Users are constantly facing the problem of deciding what to read and what to skip. Text summarization provides a practical solution to this problem, causing a resurgence in research in this field.

Given a topic of interest, a standard search often yields a large number of documents. Many of them are not of the user’s interest. Rather than going through the entire result-set, the reader may read a gist of a document, produced via summarization tools, and then decide whether to fully read the document or not, thus saving a substantial amount of time. According to Jones (2007), a summary can be defined as “a reductive transformation of source text to summary text through content reduction by selection and/or generalization on what is important in the source”. Summarization based on content reduction by selection is referred to as extraction (identifying and including the important sentences in the final summary), whereas a summary involving content reduction by generalization is called abstraction (reproducing the most informative content in a new way).

The present paper focuses on extraction-based single-document summarization. We formulate the task as a graph-based optimization problem, where vertices represent the sentences and edges the connections between sentences. Textual entailment (Giampiccolo et al., 2007) is employed to estimate the degree of connectivity between sentences, and subsequently to assign a weight to each vertex of the graph. Then, the Weighted Minimum Vertex Cover, a classical graph algorithm, is used to find the minimal set of vertices (that is – sentences) that forms a cover. The idea is that such cover of well-connected vertices would correspond to a cover of the salient content of the document.

The rest of the paper is organized as follows: In Section 2, we discuss related work and describe the wMVC algorithm. In Section 3, we propose a novel summarization method, and in Section 4, experiments and results are presented. Finally, in Section 5, we conclude and outline future research directions.

2 Background

Extractive text summarization is the task of identifying those text segments which provide important information about the gist of the document – the salient units of the text. In (Marcu, 2008), salient units are determined as the ones that contain frequently-used words, contain words that are within titles and headings, are located at the beginning or at the end of sections, contain key phrases and are the most highly connected to other parts
of the text. In this work we focus on the last of
the above criteria, connectivity, to find highly con-
ected sentences in a document. Such sentences
often contain information that is found in other
sentences, and are therefore natural candidates to
be included in the summary.

2.1 Related Work

The connectivity between sentences has been pre-
viously exploited for extraction-based summariza-
tion. Salton et al. (1997) generate intra-document
links between passages of a document using auto-
matic hypertext link generation algorithms. Mani
and Bloedorn (1997) use the number of shared
words, phrases and co-references to measure con-
nectingness among sentences. In (Barzilay and El-
hadad, 1999), lexical chains are constructed based
on words relatedness.

Textual entailment (TE) was exploited recently
for text summarization in order to find the highly
connected sentences in the document. Textual en-
tailment is an asymmetric relation between two
text fragments specifying whether one fragment
is entailed by the other. Tatar et al. (2008)
have proposed a method called Logic Text Tiling
(LTT), which uses TE for sentence scoring that
is equal to the number of entailed sentences and
to form text segments comprising of highly con-
nected sentences. Another method called Ana-
log Textual Entailment and Spectral Clustering
(ATESC), suggested in (Gupta et al., 2012), also
uses TE for sentence scoring, using analog scores.

We use a graph-based algorithm to produce the
summary. Graph-based ranking algorithms have
been employed for text summarization in the past,
with similar representation to ours. Vertices rep-
resent text units (words, phrases or sentences) and
an edge between two vertices represents any kind
of relationship between two text units. Scores are
assigned to the vertices using some relevant crite-
ria to select the vertices with the highest scores.
In (Mihalcea and Tarau, 2004), content overlap
between sentences is used to add edges between
two vertices and Page Rank (Page et al., 1999) is
used for scoring the vertices. Erkan and Radev
(2004) use inter-sentence cosine similarity based
on word overlap and tf-idf weighting to identify
relations between sentences. In our paper, we use
TE to compute connectivity between nodes of the
graph and apply the weighted minimum vertex
cover (wMVC) algorithm on the graph to select
the sentences for the summary.

2.2 Weighted MVC

wMVC is a combinatorial optimization problem
listed within the classical NP-complete problems
(Garey and Johnson, 1979; Cormen et al., 2001).
Over the years, it has caught the attention of many
researchers, due to its NP-completeness, and also
because its formulation complies with many real
world problems.

Weighted Minimum Vertex Cover Given a
weighted graph \( G = (V, E, w) \), such that \( w \) is
a positive weight (cost) function on the vertices,
\( w : V \rightarrow \mathbb{R} \), a weighted minimum vertex cover of
\( G \) is a subset of the vertices, \( C \subseteq V \) such that for
every edge \((u, v) \in E\) either \( u \in C \) or \( v \in C \)
(or both), and the total sum of the weights is min-
imized.

\[
C = \arg\min_{C'} \sum_{v \in C'} w(v) \tag{1}
\]

3 Weighted MVC for text summarization

We formulate the text summarization task as a
wMVC problem. The input document to be sum-
marized is represented as a weighted graph \( G =
(V, E, w) \), where each of \( v \in V \) corresponds to a
sentence in the document; an edge \((u, v) \in E\) ex-
ists if either \( u \) entails \( v \) or \( v \) entails \( u \) with a value
at least as high as an empirically-set threshold. A
weight \( w \) is then assigned to each sentence based
on (negated) TE values (see Section 3.2 for further
details). wMVC returns a cover \( C \) which is a sub-
set of the sentences with a minimum total weight,
corresponding to the best connected sentences in
the document. The cover is our output – the sum-
mary of the input document.

Our proposed method, shown in Figure 1, con-
sists of the following main steps.

1. Intra-sentence textual entailment score com-
putation
2. Entailment-based connectivity scoring
3. Entailment connectivity graph construction
4. Application of wMVC to the graph

We elaborate on each of these steps in the fol-
lowing sections.

3.1 Computing entailment scores

Given a document \( d \) for which summary is to be
generated, we represent \( d \) as an array of sentences
Mandela, the 70-year-old leader of the ANC jailed 27 years ago, was sentenced to life in prison for conspiring to overthrow the South African government. He was transferred from prison to a hospital in August for treatment of tuberculosis.

“There are very strong rumors in South Africa today that on Nov. 15 Nelson Mandela will be released,” said Yusuf Saloojee, chief representative in Canada for the ANC, which is fighting to end white-minority rule in South Africa. A South African government source last week indicated recent rumours of Mandela’s impending release were orchestrated by members of the anti-apartheid movement to pressure the government into taking some action. And a prominent anti-apartheid activist in South Africa said there has been “no indication (Mandela) would be released today or in the near future.”

A representative of the African National Congress said Saturday the South African government may release black nationalist leader Nelson Mandela as early as Tuesday.

Apartheid is South Africa’s policy of racial separation.

There has been wide speculation that Mandela may be released by Christmas in a move to win strong international support for the South African government.

Table 1: The sentence array of article AP881113-0007 of cluster do106 in the DUC’02 dataset.

Table 2: The sentence entailment matrix of the example article.

Table 3: Connectivity Scores of the sentences of article AP881113-0007.

3.2 Connectivity scores

Our assumption is that entailment between sentences indicates connectivity, that – as mentioned above – is an indicator of sentence salience. More specifically, salience of a sentence is determined by the degree by which it entails other sentences in the document. We thus use the sentence entailment matrix to compute a connectivity score for each sentence by summing the entailment scores of the sentence with respect to the rest of the sentences in the document, and denote this sum as \( \text{ConnScore} \). Formally, \( \text{ConnScore} \) for sentence \( i \) is computed as follows.

\[
\text{ConnScore}[i] = \sum_{i \neq j} SE[i, j]
\]  

Applying it to each sentence in the document, we obtain the \( \text{ConnScore}_{1 \times N} \) vector. The sentence connectivity scores corresponding to Table 2 are shown in Table 3.

3.3 Entailment connectivity graph construction

The more a sentence is connected, the higher its connectivity score. To adapt the scores to the wMVC algorithm, that searches for a minimal solution, we convert the scores into positive weights.
in inverted order:

\[ w[i] = -\text{ConnScore}[i] + Z \quad (3) \]

\( w[i] \) is the score that is assigned to the vertex of sentence \( i \); \( Z \) is a large constant, meant to keep the scores positive. In this paper, \( Z \) has been assigned value = 100. Now, the better a sentence is connected, the lower its weight.

Given the weights, we construct an undirected weighted entailment connectivity graph, \( G(V, E, w) \), for the document \( d \). \( V \) consists of vertices for the document’s sentences, and \( E \) are edges that correspond to the entailment relations between the sentences. \( w \) is the weight explained above. We create an edge between two vertices as explained below. Suppose that \( S_i \) and \( S_j \) are two sentences in \( d \), with entailment scores \( SE[i, j] \) and \( SE[j, i] \) between them. We set a threshold \( \tau \) for the entailment scores as the mean of all entailment values in the matrix \( SE \). We add an edge \((i, j)\) to \( G \) if \( SE[i, j] \geq \tau \) OR \( SE[j, i] \geq \tau \), i.e. if at least one of them is as high as the threshold.

Figure 2 shows the connectivity graph constructed for the example in Table 1.

![Figure 2: The Entailment connectivity graph of the considered example with associated Score of each node shown.](image)

### 3.4 Applying W MVC

Finally, we apply the weighted minimum vertex cover algorithm to find the minimal vertex cover, which would be the document’s summary. We use integer linear programming (ILP) for finding a minimum cover. This algorithm is a 2-approximation for the problem, meaning it is an efficient (polynomial-time) algorithm, guaranteed to find a solution that is no more than 2 times bigger than the optimal solution.\(^1\) The algorithm’s input is \( G = (V, E, w) \), a weighted graph where each vertex \( v_i \in V(1 \leq i \leq n) \) has weight \( w_i \). Its output is a minimal vertex cover \( C \) of \( G \), containing a subset of the vertices \( V \). We then list these sentences as our summary, according to their original order in the document.

After applying wMVC to the graph in Figure 2, the cover \( C \) returned by the algorithm is \{\( S_2, S_4, S_7, S_9 \)\} (highlighted in Figure 2).

Whenever a summary is required, a word-limit on the summary is specified. We find the threshold which results with a cover that matches the word limit through binary search.

### 4 Experiments and results

#### 4.1 Experimental settings

We have conducted experiments on the single-document summarization task of the DUC 2002 dataset\(^2\), using a random sample that contains 60 news articles picked from each of the 60 clusters available in the dataset. The target summary length limit has been set to 100 words. We used version 2.1.1 of BIUTEE (Stern and Dagan, 2012), a transformation-based TE system to compute textual entailment score between pairs of sentences.\(^3\) BIUTEE was trained with 600 text-hypothesis pairs of the RTE-5 dataset (Bentivogli et al., 2009).

#### 4.1.1 Baselines

We have compared our method’s performance with the following re-implemented methods:

1. **Sentence selection with tf-idf**: In this baseline, sentences are ranked based on the sum of the tf-idf scores of all the words except stopwords they contain, where \( idf \) figures are computed from the dataset of 60 documents. Top ranking sentences are added to the summary one by one, until the word limit is reached.

2. **LTT**: (see Section 2)

3. **ATESC**: (see Section 2)

#### 4.1.2 Evaluation metrics

We have evaluated the method’s performance using ROUGE (Lin, 2004). ROUGE measures the

\(^1\)We have used an implementation of ILP for wMVC in MATLAB, `grMinVerCover`.

\(^2\)Available at: [http://www.cs.biu.ac.il/~nlp/downloads/biutee](http://www.cs.biu.ac.il/~nlp/downloads/biutee)

quality of an automatically-generated summary by comparing it to a “gold-standard”, typically a human generated summary. ROUGE-n measures n-gram precision and recall of a candidate summary with respect to a set of reference summaries. We compare the system-generated summary with two reference summaries for each article in the dataset, and show the results for ROUGE-1, ROUGE-2 and ROUGE-SU4 that allows skips within n-grams. These metrics were shown to perform well for single document text summarization, especially for short summaries. Specifically, Lin and Hovy (2003) showed that ROUGE-1 achieves high correlation with human judgments.\(^4\)

4.2 Results

The results for ROUGE-1, ROUGE-2 and ROUGE-SU4 are shown in Tables 4, 5 and 6, respectively. For each, we show the precision (P), recall (R) and \(F_1\) scores. Boldface marks the highest score in each table. As shown in the tables, our method achieves the best score for each of the three metrics.

4.3 Analysis

The entailment connectivity graph generated conveys information about the connectivity of sentences in the document, an important parameter for indicating the salience of a sentences.

The purpose of the W MVC is therefore to find a subset of the sentences that are well-connected and cover all the content of all the sentences. Note that merely selecting the sentences on the basis of a greedy approach, that picks the those sentences with the highest connectivity score, does not ensure that all edges of the graph are covered, i.e. it does not ensure that all the information is covered in the summary. In Figure 3, we illustrate the difference between W MVC (left) and a greedy algorithm (right) over our example document. The vertices selected by each algorithm are highlighted. The selected set by W MVC, \(\{S_2, S_4, S_7, S_9\}\), covers all the edges in the graph. In contrast, using the greedy algorithm, the subset of vertices selected on the basis of highest scores is \(\{S_2, S_3, S_7, S_8\}\). There, several edges are not covered (e.g. \((S_1 \rightarrow S_9)\)).

It is therefore much more in sync with the summarization goal of finding a subset of sentences that conveys the important information of the document in a compressed manner.

Figure 3: Minimum Vertex Cover vs. Greedy selection of sentences.

5 Conclusions and future work

The paper presents a novel method for single-document extractive summarization. We formulate the summarization task as an optimization problem and employ the weighted minimum vertex cover algorithm on a graph based on textual entailment relations between sentences. Our method has outperformed previous methods that employed TE for summarization as well as a frequency-based baseline. For future work, we wish to apply our algorithm on smaller segments of the sentences, using partial textual entailment (Levy et al., 2013), where we may obtain more reliable entailment measurements, and to apply the same approach for multi-document summarization.

---
