#### Abstract

We study the problem of embedding weighted graphs of pathwidth $k$ into $\ell_{p}$ spaces. Our main result is an $O\left(k^{\min \{1 / p, 1 / 2\}}\right)$-distortion embedding. For $p=1$, this is a super-exponential improvement over the best previous bound of Lee and Sidiropoulos. Our distortion bound is asymptotically tight for any fixed $p>1$.

Our result is obtained via a novel embedding technique that is based on low depth decompositions of a graph via shortest paths. The core new idea is that given a geodesic shortest path $P$, we can probabilistically embed all points into 2 dimensions with respect to $P$. For $p>2$ our embedding also implies improved distortion on bounded treewidth graphs $\left(O\left((k \log n)^{1 / p}\right)\right)$. For asymptotically large $p$, our results also implies improved distortion on graphs excluding a minor.

## 1 INTRODUCTION

Low-distortion metric embeddings are a crucial component in the modern algorithmist toolkit. Indeed, they have applications in approximation algorithms [27], online algorithms [7], distributed algorithms [21], and for solving linear systems and computing graph sparsifiers [33]. Given a (finite) metric space ( $V, d$ ), a map

[^0]$\phi: V \rightarrow \mathbb{R}^{D}$, and a norm $\|\cdot\|$, the contraction and expansion of the map $\phi$ are the smallest $\tau, \rho \geq 1$, respectively, such that for every pair $x, y \in V$,
$$
\frac{1}{\tau} \leq \frac{\|\phi(x)-\phi(y)\|}{d(x, y)} \leq \rho .
$$

The distortion of the map is then $\tau \cdot \rho$ In this paper we will investigate embeddings into $\ell_{p}$ norms; the most prominent of which are the Euclidean norm $\ell_{2}$ and the cut norm $\ell_{1}$; the former for obvious reasons, and the latter because of its close connection to graph partitioning problems, and in particular the Sparsest Cut problem. Specifically, the ratio between the Sparsest Cut and the multicommodity flow equals the distortion of the optimal embedding into $\ell_{1}$ (see [16, 27] for more details).
We focus on embedding of metrics arising from certain graph families. Indeed, since general $n$-point metrics require $\Omega(\log n / p)$ distortion to embed into $\ell_{p}$-norms, much attention was given to embeddings of restricted graph families that arise in practice. (Embedding an (edge-weighted) graph is short-hand for embedding the shortest path metric of the graph generated by these edge-weights.) Since the class of graphs embeddable with some distortion into some target normed space is closed under taking minors, it is natural to focus on minor-closed graph families. A long-standing conjecture in this area is that all non-trivial minor-closed families of graphs embed into $\ell_{1}$ with distortion depending only on the graph family and not the size $n$ of the graph.

While this question remains unresolved in general, there has been some progress on special classes of graphs. The class of outerplanar graphs (which exclude $K_{2,3}$ and $K_{4}$ as a minor) embeds isometrically into $\ell_{1}$; this follows from results of Okamura and Seymour [31]. Following [16], Chakrabarti et al. [12] show that every graph with treewidth-2 (which excludes $K_{4}$ as a minor) embeds into $\ell_{1}$ with distortion 2 (which is tight, as shown by [24]). Lee and Sidiropoulos [26] showed that every graph with pathwidth $k$ can be embedded into $\ell_{1}$ with distortion $(4 k)^{k^{3}+1}$. See Section 1.3 for additional results.

We note that $\ell_{2}$ is a potentially more natural and useful target space than $\ell_{1}$ (in particular, finite subsets of $\ell_{2}$ embed isometrically into $\ell_{1}$ ). Alas, there are only few (natural) families of metrics that admit constant distortion embedding into Euclidean space, such as "snowflakes" of a doubling metrics [6], doubling trees [14] and graphs of bounded bandwidth [8]. All these families have bounded doubling dimension. (For definitions, see Section 2.)

Table 1: Our and previous results for embedding certain graph families into $\ell_{p}$. (For $H$-minor-free graphs, $g(H)$ is some function of $|H|$.)

| Graph Family | Our results. | Previous results |  |
| :--- | :--- | :--- | ---: |
| Pathwidth $k$ | $O\left(k^{1 / p}\right)$ | $(4 k)^{k^{3}+1}$ into $\ell_{1}$ | $[26]$ |
| Treewidth $k$ | $O\left((k \log n)^{1 / p}\right)$ | $O\left(k^{1-1 / p} \cdot \log ^{1 / p} n\right)$ | $[22]$ |
|  |  | $O\left((\log (k \log n))^{1-1 / p}\left(\log ^{1 / p} n\right)\right)$ | $[20]$ |
| Planar | $O\left(\log ^{1 / p} n\right)$ | $O\left(\log ^{1 / p} n\right)$ | $[32]$ |
| $H$-minor-free | $O\left((g(H) \log n)^{1 / p}\right)$ | $O\left(\|H\|^{1-1 / p} \log ^{1 / p} n\right)$ | $[4]+[22]$ |

### 1.1 Our Results

In this paper we develop a new technique for embedding certain graph families into $\ell_{p}$ spaces with constant distortion. Our main result is an improved embedding for bounded pathwidth graphs (see Section 2 for the definition of pathwidth and other graph families).

Theorem 1.1 (Рathwidth Theorem). Any graph with pathwidth $k$ embeds into $\ell_{p}$ with distortion $O\left(k^{1 / p}\right)$.

Note that this is a super-exponential improvement over the best previous distortion bound of $O(k)^{k^{3}}$, by Lee and Sidiropoulos. Their approach was based on probabilistic embedding into trees, which implies embedding only into $\ell_{1}$. Such an approach cannot yield distortion better than $O(k)$, due to known lower bounds for the diamond graph [16], that has pathwidth $k+1$. Our embedding holds for any $\ell_{p}$ space, and we can overcome the barrier of $O(k)$ (since finite subsets of $\ell_{2}$ embed isometrically into $\ell_{p}$, the distortion of Theorem 1.1 is never larger than $O(\sqrt{k})$ ). In particular, we obtain embeddings of pathwidth- $k$ graphs into both $\ell_{2}$ and $\ell_{1}$ with distortion $O(\sqrt{k})$. Moreover, an embedding with this distortion can be found efficiently via semidefinite-programming; see, e.g., [27], even without access to the actual path decomposition (which is NPhard even to approximate [9]). We remark that graphs of bounded pathwidth can have arbitrarily large doubling dimension (exhibited by star graphs that have pathwidth 1 ), and thus our result is a noteworthy example of a non-trivial Euclidean embedding with constant distortion for a family of metrics with unbounded doubling dimension

Since graphs of treewidth $k$ have pathwidth $O(k \log n)$ (see, e.g., [17]), Theorem 1.1 provides an embedding of such graphs into $\ell_{p}$ with distortion $O\left((k \log n)^{1 / p}\right)$. This strictly improves the best previously known bound, which follows from a theorem in [22] (who obtained distortion $\left.O\left(k^{1-1 / p} \log ^{1 / p} n\right)\right)$, for any $p>2$, and matches it for $1 \leq p \leq 2$. While [20] obtained recently a distortion bound with improved dependence on $k$, their result $O\left((\log (k \log n))^{1-1 / p}\left(\log ^{1 / p} n\right)\right)$ has sub-optimal dependence on $n$.

A General Embedding Framework. The embedding of Theorem 1.1 follows as a special case of a more general theorem: we devise embeddings for any graph family which admits "shortest path decompositions" (SPDs) of "low depth". Every (weighted) path graph has an SPD of depth 1. A graph $G$ has an SPD of depth $k$ if after removing some shortest path $P$, every connected component in $G \backslash P$ has an SPD of depth $k-1$. (An alternative definition appears in Definition 3.1.) Our main technical result is the following.

Theorem 1.2 (Embeddings for SPD Families). Let $G=(V, E)$ be a weighted graph with an SPD of depth $k$. Then there exists an embedding $f: V \rightarrow \ell_{p}$ with distortion $O\left(k^{1 / p}\right)$.

Since bounded-pathwidth graphs admit SPDs of low depth, we get Theorem 1.1 as a simple corollary of Theorem 1.2. Moreover, we derive several other results, which are summarized in Table 1; these results either improve on the state-of-the-art, or provide matching bounds using a new approach.

Our result of Theorem 1.1 (and thus also Theorem 1.2) is asymptotically tight for any fixed $p>1$. The family exhibiting this fact is the diamond graphs.

Theorem 1.3 ([23, 28, 30]). For any fixed $p>1$ and every $k \geq 1$, there exists a graph $G=(V, E)$ with pathwidth- $k$, such that every embedding $f: V \rightarrow \ell_{p}$ has distortion $\Omega\left(k^{\min \left\{1 / p, 1_{2}^{1 / 2}\right\}}\right)$.

The bound in Theorem 1.3 was proven first for $p=2$ in [30], generalized to $1<p \leq 2$ in [23] and for $p \geq 2$ by [28] (see also [18, 19]). The proofs of [23, 30] were done using the diamond graph, while [28] used the Laakso graph. For completeness, we provide a proof of the case $p \geq 2$ using the diamond graph in Section 8 . We note that for $\ell_{1}$ only the trivial $\Omega(\log k)$ lower bound is known.

### 1.2 Technical Ideas

Many known embeddings [1, 10, 22, 32] are based on a collection of 1-dimensional embeddings, where we embed each point to its distance from a given subset of points. We follow this approach, but differ in two aspects. Firstly, the subset of points we use is not based on random sampling or probabilistic clustering. Rather, inspired by the works of [5] and [4], the subset used is a geodesic shortest path. The second is that our embedding is not 1-dimensional but 2-dimensional: this seemingly small change crucially allows us to use the structure of the shortest paths to our advantage.

The SPD induces a collection of shortest paths (each shortest path lies in some connected component). A natural initial attempt is to embed a vertex $v$ relative to a geodesic path $P$ using two dimensions: ${ }^{1}$

- The first coordinate $\Delta_{1}$ is the distance to the path $d(v, P)$.
- The second coordinate $\Delta_{2}$ is the distance $d(v, r)$ to the endpoint of the path, called its "root".

[^1]

Figure 1: A shortest path $P$, rooted at $r$, partitions cluster $X$ into clusters $C_{1}$ and $C_{2}$. In cases (a) and (b), the first coordinate (the distance to $P$ ) provides sufficient contribution. In case (c) the second coordinate (the distance to root $r$ ) provides the contribution.

Figure 2: An illustration of our initial attempt. The first coordinate $\Delta_{1}$ is the distance to the path $d(v, P)$. The second coordinate $\Delta_{2}$ is the distance $d(v, r)$ to the endpoint of the path, called its "root".

Unfortunately, this embedding may have unbounded expansion: If two vertices $u, v$ are separated by some shortest path, in future iterations $v$ may have a large distance to the root of a path $P$ in its component, while $u$ has zero in that coordinate (because it's not in that component), incurring a large stretch. The natural fix is to enforce a Lipschitz condition on every coordinate: for $v$ in cluster $X$, we truncate the value $v$ can receive at $O\left(d_{G}(v, V \backslash X)\right.$ ). I.e., a vertex close to the boundary of $X$ cannot get a large value. Using the fact that the SPD has depth $k$, each vertex will have only $O(k)$ nonzero coordinates, which implies expansion $O\left(k^{1 / p}\right)$.

To bound the contraction, for each pair $u, v$ we consider the first path $P$ in the SPD that lies "close" to $\{u, v\}$ or separates them to different connected components. Then we show that at least one of the two coordinates should give sufficient contribution.

But what about the effect of truncation on contraction? A careful recursive argument shows that the contribution to $u, v$ from the first coordinate (the distance from the path $P$ ) is essentially not affected by this truncation. Hence the argument in cases (a) and (b) of Figure 1 still works. However, the argument using the distance to the root of $P$, case (c), can be ruined. Solving this issue requires some new non-trivial ideas. Our solution is to introduce a probabilistic sawtooth function that replaces the simple truncation. The main technical part of the paper is devoted to showing that a collection of these functions for all possible distance scales, with appropriate random shifts, suffices to control the expected contraction in case (c), for all relevant pairs simultaneously.

### 1.3 Other Related Work

There has been work on embedding several other graph families into normed spaces: Chekuri et al. [13] extend the Okamura and Seymour bound for outerplanar graphs to $k$-outerplanar graphs, and showed that these embed into $\ell_{1}$ with distortion $2^{O(k)}$. Rao [32] (see also [22]) embed planar graphs into $\ell_{p}$ with distortion $O\left(\log ^{1 / p} n\right)$. For graphs with genus $g$, [25] showed an embedding into Euclidean space with distortion $O(\log g+\sqrt{\log n})$. Finally, for $H$-minor-free
graphs, combining the results of $[4,22]$ give $\ell_{p}$-embeddings with $O\left(|H|^{1-1 / p} \log ^{1 / p} n\right)$ distortion.

Following [5, 29], the idea of using geodesic shortest paths to decompose the graph has been used for many algorithmic tasks: MPLS routing [15], directed connectivity, distance labels and compact routing [34], object location [3], and nearest neighbor search [2]. However, to the best of our knowledge, this is the first time it has been used directly for low-distortion embeddings into normed spaces.

## 2 PRELIMINARIES AND NOTATION

For $k \in \mathbb{Z}$, let $[k]:=\{1, \ldots, k\}$. For $p \geq 1$, the $\ell_{p}$-norm of a vector $x=\left(x_{1}, \ldots, x_{d}\right) \in \mathbb{R}^{d}$ is $\|x\|_{p}:=\left(\sum_{i=1}^{d}\left|x_{i}\right|^{p}\right)^{1 / p}$, where $\|x\|_{\infty}:=\max _{i}\left|x_{i}\right|$.

Doubling dimension. The doubling dimension of a metric is a measure of its local "growth rate". Formally, a metric space ( $X, d$ ) has doubling dimension $\lambda_{X}$ if for every $x \in X$ and radius $r$, the ball $B(x, r)$ can be covered by $2^{\lambda_{X}}$ balls of radius $\frac{r}{2}$. A family is doubling if the doubling dimension of all metrics in it is bounded by some universal constant.

Graphs. We consider connected undirected graphs $G=(V, E)$ with edge weights $w: E \rightarrow \mathbb{R}_{>0}$. Let $d_{G}$ denote the shortest path metric in $G$; we drop subscripts when there is no ambiguity. For a vertex $x \in V$ and a set $A \subseteq V$, let $d_{G}(x, A):=\min _{a \in A} d(x, a)$, where $d_{G}(x, \emptyset):=\infty$. For a subset of vertices $A \subseteq V$, let $G[A]$ denote the induced graph on $A$, and let $d_{A}:=d_{G[A]}$ be the shortest path metric in the induced graph. Let $G \backslash A:=G[V \backslash A]$ be the graph after deleting the vertex set $A$ from $G$.

Special graph families. Given a graph $G=(V, E)$, a tree decomposition of $G$ is a tree $T$ with nodes $B_{1}, \ldots, B_{s}$ (called bags) where each $B_{i}$ is a subset of $V$ such that the following properties hold:

- For every edge $\{u, v\} \in E$, there is a bag $B_{i}$ containing both $u$ and $v$.
- For every vertex $v \in V$, the set of bags containing $v$ form a connected subtree of $T$.
The width of a tree decomposition is $\max _{i}\left\{\left|B_{i}\right|-1\right\}$. The treewidth of $G$ is the minimal width of a tree decomposition of $G$.

A path decomposition of $G$ is a special kind of tree decomposition where the underlying tree is a path. The pathwidth of $G$ is the minimal width of a path decomposition of $G$.

A graph $H$ is a minor of a graph $G$ if we can obtain $H$ from $G$ by edge deletions/contractions, and vertex deletions. A graph family $\mathcal{G}$ is $H$-minor-free if no graph $G \in \mathcal{G}$ has $H$ as a minor.

### 2.1 The Sawtooth Function

Another component in our embeddings will be the following sawtooth function. For $t \in \mathbb{N}$, we define $g_{t}: \mathbb{R}_{+} \rightarrow \mathbb{R}$ the sawtooth function w.r.t. $2^{t}$ as follows. For $x \geq 0$, if $q_{x}:=\left\lfloor x / 2^{t+1}\right\rfloor$ then

$$
g_{t}(x)=2^{t}-\left|x-\left(q_{x} \cdot 2^{t+1}+2^{t}\right)\right|
$$

Figure 3: The graph of the "sawtooth" function $g_{t}$. The points $x_{1}=$ $5 \cdot 2^{t-1}$ and $x_{3}=15 \cdot 2^{t-1}$ are mapped to $2^{t-1}$, while $x_{2}=10 \cdot 2^{t-1}$ is mapped to $2^{t}$.

## The following observation is straightforward.

Observation 1. The Sawtooth function $g_{t}$ is 1-Lipschitz, bounded by $2^{t}$, periodic with period $2^{t+1}$.

The proof of the following lemma appears in Section 7.
Lemma 2.1 (Sawtooth Lemma). Let $x, y \in \mathbb{R}_{+}$. Let $\alpha \in[0,1]$, $\beta \in[0,4]$ be drawn uniformly and independently. The following properties hold:
(1) $\mathbb{E}_{\alpha, \beta}\left[g_{t}\left(\beta x+\alpha \cdot 2^{t+1}\right)\right]=2^{t-1}$.
(2) If $|x-y| \leq 2^{t-1}$, then $\mathbb{E}_{\alpha, \beta}\left[\left|g_{t}\left(\beta x+\alpha \cdot 2^{t+1}\right)-g_{t}\left(\beta y+\alpha \cdot 2^{t+1}\right)\right|\right]=\Omega(|x-y|)$.
(3) If $|x-y|>2^{t-1}$, then $\mathbb{E}_{\alpha, \beta}\left[\left|g_{t}\left(\beta x+\alpha \cdot 2^{t+1}\right)-g_{t}\left(\beta y+\alpha \cdot 2^{t+1}\right)\right|\right]=\Omega\left(2^{t}\right)$.

## 3 SHORTEST PATH DECOMPOSITIONS

Our embeddings will crucially depend on the notion of shortest path decompositions. In the introduction we provided a recursive definition for SPD. Here we show an equivalent definition which will be more suitable for our purposes.

Definition 3.1 (Shortest Path Decomposition (SPD)). Given a weighted graph $G=(V, E, w)$, a SPD of depth $k$ is a pair $\{\mathcal{X}, \mathcal{P}\}$, where $\mathcal{X}$ is a collection $\mathcal{X}_{1}, \ldots, X_{k}$ of partial partitions of $V^{2}$, and $\mathcal{P}$ is a collection of sets of paths $\mathcal{P}_{1}, \ldots, \mathcal{P}_{k}$, where $\mathcal{X}_{1}=\{V\}, \mathcal{X}_{k}=\mathcal{P}_{k}$, and the following properties hold:
(1) For every $1 \leq i \leq k$ and every subset $X \in X_{i}$, there exist a unique path $P_{X} \in \mathcal{P}_{i}$ such that $P_{X}$ is a shortest path in $G[X]$.
(2) For every $2 \leq i \leq k, X_{i}$ consists of all connected components of $G\left[X \backslash P_{X}\right]$ over all $X \in X_{i-1}$.
In other words, $\bigcup_{i=1}^{k} \mathcal{P}_{k}$ is a partition of $V$ into paths, where each path $P_{X}$ is a shortest path in the component $X$ it belongs to at the point it is deleted.

For a given graph $G$ let SPDdepth $(G)$ be the minimum $k$ such that $G$ admits an SPD of depth $k$. For a given family of graphs $\mathcal{G}$

[^2]let SPDdepth $(\mathcal{G}):=\max _{G \in \mathcal{G}}\{\operatorname{SPDdepth}(G)\}$. In the following we consider the SPDdepth of some graph families.

### 3.1 The SPD Depth for Various Graph Families

One advantage of defining the shortest path decomposition is that several well-known graph families have bounded depth SPD.

- Pathwidth. Every graph $G=(V, E, w)$ with pathwidth $k$ has an SPDdepth of $k+1$. Indeed, let $\mathcal{T}=\left\langle\mathcal{B}_{1}, \ldots, \mathcal{B}_{s}\right\rangle$ be a path decomposition of $G$, where $\mathcal{B}_{1}, \mathcal{B}_{s}$ are the two bags at the end of this path. Choose arbitrary vertices $x \in \mathcal{B}_{1}$ and $y \in \mathcal{B}_{s}$, and let $P$ be a shortest path in $G$ from $x$ to $y$. By the definition of a path decomposition, the path $P$ contains at least one vertex from every bag $\mathcal{B}_{i}$. Hence, deleting the vertices of $P$ would reduce the size of each bag by one; consequently each connected component of $G \backslash P$ has pathwidth $k-1$, and by induction SPDdepth $k$. Finally, a connected component of pathwidth 0 is necessarily a singleton, which has SPDdepth 1.
- Treewidth. Since every tree has pathwidth $O(\log n)$, we can show that an $n$-vertex treewidth- $k$ graph has pathwidth $O(k \log n)$. Hence, treewidth- $k$ graphs have SPDdepth $O(k \log n)$.
- Planar. Using cycle separators [29] as in [15, 34], every planar graph has SPDdepth $O(\log n)$; this follows as each cycle separator can be constructed as union of two shortest paths.
- Minor-free. Finally, every $H$-minor-free graph admits a balanced separator consisting of $g(H)$ shortest paths (for some function $g$ ) [3], and hence has an SPDdepth $O(g(H) \cdot \log n)$.

Combining these observation with Theorem 1.2, we get the following set of results:

Corollary 3.2. Consider an n-vertex weighted graph G, Theorem 1.2 implies the following:

- If $G$ has pathwidth $k$, it embeds into $\ell_{p}$ with distortion $O\left(k^{1 / p}\right)$.
- If $G$ has treewidth $k$, it embeds into $\ell_{p}$ with distortion $O\left((k \log n)^{1 / p}\right)$.
- If $G$ is planar, it embeds into $\ell_{p}$ with distortion $O\left(\log ^{1 / p} n\right)$.
- For every fixed $H$, if $G$ excludes $H$ as a minor, it embeds into $\ell_{p}$ with distortion $O\left(\log ^{1 / p} n\right)$, where the constant in the big-O depends on $H$.

As mentioned in Section 1, we get a substantial improvement for the pathwidth case. Our result for treewidth improves upon that from [22] for $p>2$; they got $O\left(k^{1-1 / p}(\log n)^{1 / p}\right)$ distortion compared to our $O\left((k \log n)^{1 / p}\right)$. Our result appears to be closer to the truth, since the distortion tends to $O(1)$ as $p \rightarrow \infty$.

Finally, our results for planar graphs match the current state-of-the-art.

Our results for minor-free graphs depend on the RobertsonSeymour decomposition, and hence are currently better only for large values of $p$. (It remains an open question to improve the SPDdepth of $H$-minor-free graphs to have a poly $(|H|) \log n$ dependence, perhaps using the ideas from [4].) In general, we hope that our results will be useful in getting other embedding results, and will spur further work on understanding shortest path separators.

## 4 THE EMBEDDING ALGORITHM

Let $G=(V, E)$ be a weighted graph, and let $\{\mathcal{X}, \mathcal{P}\}=$ $\left\{\left\{X_{1}, \ldots, \mathcal{X}_{k}\right\},\left\{\mathcal{P}_{1}, \ldots, \mathcal{P}_{k}\right\}\right\}$ be an SPD of depth $k$ for $G$. By scaling, we can assume that the minimum weight of an edge is 1 ; let $M \in \mathbb{N}$ be the minimal such that the diameter of $G$ is strictly bounded by $2^{M}$. Pick $\alpha \in[0,1]$ and $\beta \in[0,4]$ uniformly and independently.

For every $i \in[k]$, and $X \in \mathcal{X}_{i}$, we now construct an embedding $f_{X}: V \rightarrow \mathbb{R}^{D}$ (for some number of dimensions $D \in \mathbb{N}$ ). This map $f_{X}$ consists of two parts.

First coordinate: Distance to the Path. The first coordinate of the embedding implements the distance to the path $P_{X}$, and is denoted by $f_{X}^{\text {path }}$. Let $X_{1}, \ldots, X_{s} \in X_{i+1}$ be the connected components of $G\left[X \backslash P_{X}\right]$ (note that it is also possible that $s=0$ ). We use a separate coordinate for each $X_{j}$, and hence $f_{X}^{\mathrm{path}}: V \rightarrow \mathbb{R}^{s}$. Moreover, for $v \in X$ we truncate at $2 d_{G}(v, V \backslash X)$ in order to guarantee Lipschitzness. In particular, the coordinate corresponding to $X_{j}$ is set to
$\left(f_{X}^{\text {path }}\right)_{X_{j}}(v)= \begin{cases}\min \left\{d_{X}\left(v, P_{X}\right), 2 d_{G}(v, V \backslash X)\right\} & \text { if } v \in X_{j}, \\ 0 & \text { otherwise. }\end{cases}$
See Figure 4 for an illustration.

Figure 4: The set $X \in X_{i}$ surrounded by a closed curve. The path $P_{X}$ partitions $X$ into $X_{1}, X_{2} \in X_{i+1}$. The embedding $f_{X}^{\text {path }}$ consists of two coordinates, and represented in the figure by a horizontal vector next to each vertex, where the first entry is w.r.t. $X_{1}$ and the second w.r.t. $X_{2}$. Each point on $P_{X}$, or not in $X$ maps to 0 in both the coordinates. Each point in $X_{1}$ maps to $\min \left\{d_{X}\left(v, P_{X}\right), 2 d_{G}(v, V \backslash X)\right\}$ in the first coordinate and to 0 in the second.

Second coordinate: Distance to the Root. The second part is denoted $f_{X}^{\text {root }}$, which is intended to capture the distance from the root $r$ of the path. Again, to get the Lipschitz-ness, we would like to truncate the value at $2 d_{G}(v, V \backslash X)$ as we did for $f_{X}^{\text {path }}$. However, a problem with this idea is that the root $r$ can be arbitrarily far from some pair $u, v$ that needs contribution from this coordinate. And hence, even if $\left|d_{G}(u, r)-d_{G}(v, r)\right| \approx d_{G}(u, v)$, there may be no contribution after the truncation. So we use the sawtooth function.

Specifically, we replace the ideal contribution $d_{G}(v, r)$ by the sawtooth function $g_{t}\left(d_{G}(v, r)\right)$, where the scale $t$ for the function is chosen such that $2^{t} \approx d_{G}(v, V \backslash X)$. To avoid the case that two nearby points use two different scales (and hence to guarantee Lipschitz-ness), we take an appropriate linear combination of the
two distance scales closest to $2 d_{G}(v, V \backslash X)$. Recall that the sawtooth function does not guarantee contribution for $u, v$ due to its periodicity: we may be unlucky and have $g_{t}\left(d_{G}(v, r)\right)=g_{t}\left(d_{G}(u, r)\right)$ even when $d_{G}(v, r)$ and $d_{G}(u, r)$ are very different. To guarantee a large enough contribution for all relevant pairs simultaneously, we add a random shift $\alpha$, and apply a random "stretch" $\beta$ to $d_{G}(v, r)$ before feeding it to $g_{t}$. Lemma 2.1 then shows that many of the choices of $\alpha$ and $\beta$ give substantially different values for $u, v$.

Formally, the mapping is as follows. The function $f_{X}^{\text {root }}$ consists of $M+1$ coordinates, one for each distance scale $t \in\{0,1, \ldots, M\}$. The coordinate corresponding to $t$ is denoted by $f_{X, t}^{\text {root }}$. Let $r$ be an arbitrary endpoint of $P_{X}$; we will call $r$ the "root" of $P_{X}$. Let $t_{v} \in \mathbb{N}$ be such that $2 d_{G}(v, V \backslash X) \in\left[2^{t_{v}}, 2^{t_{v}+1}\right)$. Set $\lambda_{v}=\frac{2 d_{G}(v, V \backslash X)-2^{t_{v}}}{2^{t_{v}}}$. Note that $0 \leq \lambda_{v}<1$. For $v \in X$, we define
$f_{X, t}^{\mathrm{root}}(v)= \begin{cases}\lambda_{v} \cdot g_{t}\left(\beta \cdot d_{X}(v, r)+\alpha \cdot 2^{t+1}\right) & \text { if } t=t_{v}+1, \\ \left(1-\lambda_{v}\right) \cdot g_{t}\left(\beta \cdot d_{X}(v, r)+\alpha \cdot 2^{t+1}\right) & \text { if } t=t_{v}, \\ 0 & \text { otherwise. }\end{cases}$

For all nodes $v \notin X$, we set $f_{X}^{\text {root }}(v)=\overrightarrow{0}$.
Define the map $f_{X}=f_{X}^{\text {path }} \oplus f_{X}^{\text {root }}$, and the final embedding is

$$
f=\bigoplus_{i=1}^{k} \bigoplus_{X \in \mathcal{X}_{i}} f_{X}
$$

i.e., the concatenation of all the constructed embeddings. Before we start the analysis, let us record some simple observations.

Observation 2. For the map $f$ defined above, the following hold:

- The number of coordinates in $f$ does not depend on $\alpha, \beta$.
- For every $X \in X_{i}$ and $v \notin X$, the $\operatorname{map} f_{X}(v)$ is the constant vector $\overrightarrow{0}$.
- For every $X \in X_{i}$ and $v \in X$, the map $f_{X}$ is nonzero in at most 3 coordinates.
Hence, since $\mathcal{X}_{i}$ is a partial partition of $V$ and the depth of the SPD is $k$, we get that $f(v)$ is nonzero in at most $3 k$ coordinates for each $v \in V$.

## 5 THE ANALYSIS

The main technical lemmas now show that the per-coordinate expansion is constant, and that for every pair, there exists a coordinate for which the expected contraction is constant.

Lemma 5.1 (Expansion Bound). For any vertices $u$, $v$, every coordinate $j$, and every choice of $\alpha, \beta$,

$$
\left|f_{j}(v)-f_{j}(u)\right|=O\left(d_{G}(u, v)\right)
$$

Lemma 5.2 (Contraction Bound). For any vertices $u$, $v$, there exists some coordinate $j$ such that

$$
\mathbb{E}_{\alpha, \beta}\left[\left|f_{j}(v)-f_{j}(u)\right|\right]=\Omega\left(d_{G}(u, v)\right)
$$

Given these two lemmas, we can combine them together to show that the entire embedding has small distortion. (Proof of the composition lemma can be found in Section 6.)

Lemma 5.3 (Composition Lemma). Let $(X, d)$ be a metric space. Suppose that there are constants $\rho, \tau$ and a function $f: X \rightarrow \mathbb{R}^{s}$, drawn from some probability space such that:
(1) For every $u, v \in X$ and every $j \in[s],\left|f_{j}(v)-f_{j}(u)\right| \leq \rho \cdot d(v, u)$.
(2) For every $u, v \in X$, there exists $j \in[s]$ such that $\mathbb{E}\left[\mid f_{j}(v)\right.$ $\left.f_{j}(u) \mid\right] \geq \frac{1}{\tau} \cdot d(v, u)$.
(3) For every $v \in X$, there is a subset of indices $I_{v} \subseteq[s]$ of size $\left|I_{v}\right| \leq k$, such that for every $j \notin I_{v}, f_{j}(v)=0$. In other words, for every $v \in X, f(v)$ has support of size at most $k$.
Then, for every $p \geq 1$, there is an embedding of $(X, d)$ into $\ell_{p}$ with distortion $O\left(k^{1 / p}\right)$. Moreover, if there is an efficient algorithm for sampling such an $f$, then there is a randomized algorithm that constructs the embedding efficiently (in expectation).

Now Theorem 1.2, our embedding for graphs with low depth SPDs, immediately follows by applying the Composition Lemma (Lemma 5.3) to Lemma 5.1, Lemma 5.2, and Observation 2.

### 5.1 Proof of Lemma 5.1

In this section we bound the expansion of any coordinate in our embedding. Recall that the embedding of $v$ lying in some component $X$ consists of two sets of coordinates: its distance from the path, and its distance from the root. As mentioned in the introduction, since points outside $X$ are mapped to zero, maintaining Lipschitz-ness requires us to truncate the contribution of $v$ of any coordinate to its distance from the boundary. This truncation (either via taking a minimum with $d_{G}(v, V \backslash X)$, or via the sawtooth function), means that our proofs of expansion require more care. Let us now give the details.

Consider any level $i$, any set $X \in X_{i}$, and any pair of vertices $u, v$. It suffices to show that $\left\|f_{X}(v)-f_{X}(u)\right\|_{\infty}=O\left(d_{G}(u, v)\right)$. To begin, we may assume that both $u, v \in X$. Indeed, if both $u, v \notin X$, then $f_{X}(v)=f_{X}(u)=\overrightarrow{0}$ and we are done. If one of them, say $v$ belongs to $X$ while the other $u \notin X$, then $f_{X}(u)=\overrightarrow{0}$ while $f_{X}(v)$ is bounded by $2^{t_{v}+1} \leq 4 d_{G}(v, V \backslash X) \leq 4 d_{G}(u, v)$ in each coordinate.

Moreover, we may also assume that the shortest $u-v$ path in $G$ contains only vertices from $X$. Indeed, suppose their shortest path in $G$ uses vertices from $V \backslash X$, then $d_{G}(u, V \backslash X)+d_{G}(v, V \backslash X) \leq$ $d_{G}(u, v)$. But since both $f_{X}(v), f_{X}(u)$ are bounded in each coordinate by $4 \cdot \max \left\{d_{G}(u, V \backslash X), d_{G}(v, V \backslash X)\right\}$, we have constant expansion. Henceforth, we can assume that $d_{G}(u, v)=d_{X}(u, v)$. We now bound the expansion in each of the two parts of $f_{X}$ separately.

Expansion of $f_{X}^{\text {path }}$. Let $X_{v}, X_{u}$ be the connected components in $G\left[X \backslash P_{X}\right]$ such that $v \in X_{v}$ and $u \in X_{u}$. Consider the first case $X_{v} \neq X_{u}$, then $P_{X}$ intersects the shortest path between $v$ and $u$. In particular,

$$
\begin{aligned}
& \left\|f_{X}^{\text {path }}(v)-f_{X}^{\text {path }}(u)\right\|_{\infty} \\
& \leq \quad \min \left\{d_{X}\left(v, P_{X}\right), 2 d_{G}(v, V \backslash X)\right\} \\
& \quad \quad+\min \left\{d_{X}\left(u, P_{X}\right), 2 d_{G}(u, V \backslash X)\right\} \\
& \leq \quad d_{X}\left(v, P_{X}\right)+d_{X}\left(u, P_{X}\right) \leq d_{X}(v, u)=d_{G}(v, u)
\end{aligned}
$$

Otherwise, $X_{v}=X_{u}$ and the two vertices lie in the same component. Now $\| f_{X}^{\text {path }}(v)$ $f_{X}^{\text {path }}(u) \|_{\infty} \quad$ equals $\quad \mid \min \left\{d_{X}\left(v, P_{X}\right), 2 d_{G}(v, V \backslash X)\right\} \quad-$ $\min \left\{d_{X}\left(u, P_{X}\right), 2 d_{G}(u, V \backslash X)\right\} \mid$. Assuming (without loss of generality) that the first term is at least the second, we can drop the absolute value signs. Now the bound on the expansion follows from
a simple case analysis. Indeed, suppose $d_{X}\left(u, P_{X}\right) \leq 2 d_{G}(u, V \backslash X)$. Then we get

$$
\begin{aligned}
& \left\|f_{X}^{\text {path }}(v)-f_{X}^{\text {path }}(u)\right\|_{\infty} \\
& \quad=\quad \min \left\{d_{X}\left(v, P_{X}\right), 2 d_{G}(v, V \backslash X)\right\}-d_{X}\left(u, P_{X}\right) \\
& \quad \leq \quad d_{X}\left(v, P_{X}\right)-d_{X}\left(u, P_{X}\right) \leq d_{X}(u, v)=d_{G}(u, v)
\end{aligned}
$$

The other case is that $d_{X}\left(u, P_{X}\right)>2 d_{G}(u, V \backslash X)$, and then

$$
\begin{aligned}
& \left\|f_{X}^{\text {path }}(v)-f_{X}^{\text {path }}(u)\right\|_{\infty} \\
& \quad=\quad \min \left\{d_{X}\left(v, P_{X}\right), 2 d_{G}(v, V \backslash X)\right\}-2 d_{G}(u, V \backslash X) \\
& \quad \leq \quad 2 d_{G}(v, V \backslash X)-2 d_{G}(u, V \backslash X) \leq 2 d_{G}(u, v)
\end{aligned}
$$

Hence the expansion is bounded by 2 .
Expansion of $f_{X}^{\text {root }}$. Let $r$ be the root of $P_{X}$. For $t \in$ $\{0,1, \ldots, M\}$, let $p_{t}$ (respectively, $q_{t}$ ) be the "weight" of $v$ (respectively, $u$ ) on $g_{t}$-in other words, $p_{t}$ is the constant in (1) such that $f_{X, t}^{\text {root }}(v)=p_{t} \cdot g_{t}\left(\beta \cdot d_{X}(v, r)+\alpha \cdot 2^{t+1}\right)$. Note that $p_{t} \in\left\{0, \lambda_{v}, 1-\lambda_{v}\right\}$ is chosen deterministically, and is nonzero for at most two indices $t$.

First, observe that for every $t$,

$$
\begin{align*}
& \left\lvert\, \begin{array}{l}
\left|f_{X, t}^{\mathrm{root}}(v)-f_{X, t}^{\mathrm{root}}(u)\right| \\
=
\end{array}\right. \\
& \begin{array}{l}
\mid p_{t} \cdot g_{t}\left(\beta \cdot d_{X}(v, r)+\alpha \cdot 2^{t+1}\right) \\
\\
\quad-q_{t} \cdot g_{t}\left(\beta \cdot d_{X}(u, r)+\alpha \cdot 2^{t+1}\right) \mid
\end{array} \\
& \begin{array}{l}
\leq \min \left\{p_{t}, q_{t}\right\} \cdot \mid g_{t}\left(\beta \cdot d_{X}(v, r)+\alpha \cdot 2^{t+1}\right) \\
\quad-g_{t}\left(\beta \cdot d_{X}(u, r)+\alpha \cdot 2^{t+1}\right)\left|+\left|p_{t}-q_{t}\right| \cdot 2^{t}\right.
\end{array} \\
& \begin{array}{l}
\leq \min \left\{p_{t}, q_{t}\right\} \cdot \beta \cdot\left|d_{X}(v, r)-d_{X}(u, r)\right|+\left|p_{t}-q_{t}\right| \cdot 2^{t} \\
\leq O\left(d_{G}(u, v)\right)+\left|p_{t}-q_{t}\right| \cdot 2^{t} .
\end{array}
\end{align*}
$$

The first inequality used that $g_{t}$ is bounded by $2^{t}$, and the second inequality that $g_{t}$ is 1-Lipschitz; both follow from Observation 1. The last inequality follows by the triangle inequality (since we assumed that the shortest path from $v$ to $u$ is contained within $X$ ).

Hence, it suffices to show that $\left|p_{t}-q_{t}\right|=O\left(d_{G}(u, v) / 2^{t}\right)$. Indeed, for indices $t \notin\left\{t_{u}, t_{u}+1, t_{v}, t_{v}+1\right\}, p_{t}=q_{t}=0$, hence $\left|p_{t}-q_{t}\right|=0$. Let us consider the other cases. W.l.o.g., assume that $d_{G}(v, V \backslash X) \geq d_{G}(u, V \backslash X)$ and hence $t_{v} \geq t_{u}$.

- $\boldsymbol{t}_{\boldsymbol{u}}=\boldsymbol{t}_{\boldsymbol{v}}:$ In this case, $\left|p_{t_{v}}-q_{t_{v}}\right|=\left|\left(1-\lambda_{v}\right)-\left(1-\lambda_{u}\right)\right|=$ $\lambda_{v}-\lambda_{u}=\left|p_{t_{v}+1}-q_{t_{v}+1}\right|$. Moreover, this quantity is

$$
\begin{aligned}
\lambda_{v}-\lambda_{u} & =\frac{2 d_{G}(v, V \backslash X)-2^{t}}{2^{t}}-\frac{2 d_{G}(u, V \backslash X)-2^{t}}{2^{t}} \\
& =\frac{2\left(d_{G}(v, V \backslash X)-d_{G}(u, V \backslash X)\right)}{2^{t}} \\
& \leq \frac{2 d_{G}(u, v)}{2^{t}}
\end{aligned}
$$

Hence, we get that $\left|p_{t}-q_{t}\right|=O\left(d_{G}(u, v) / 2^{t}\right)$ for both $t \in$ $\left\{t_{v}, t_{v}+1\right\}$.

- $t_{u}=t_{v}-1:$ It holds that

$$
\begin{aligned}
\lambda_{v} & +\left(1-\lambda_{u}\right) \\
& \leq 2 \cdot \frac{2 d_{G}(v, V \backslash X)-2^{t_{v}}}{2^{t_{v}}}+\frac{2^{t_{u}+1}-2 d_{G}(u, V \backslash X)}{2^{t_{u}}} \\
& =\frac{2 d_{G}(v, V \backslash X)-2 d_{G}(u, V \backslash X)}{2^{t_{u}}} \leq \frac{2 d_{G}(u, v)}{2^{t_{u}}}
\end{aligned}
$$

If we define $\chi:=\lambda_{v}+\left(1-\lambda_{u}\right)$, we conclude that

$$
\begin{aligned}
& \left|p_{t_{v}+1}-q_{t_{v}+1}\right|=\quad \lambda_{v} \leq \chi=O\left(d_{G}(u, v) / 2^{t_{v}+1}\right) \\
& \left|p_{t_{v}}-q_{t_{v}}\right|=\left|1-\lambda_{v}-\lambda_{u}\right| \leq \chi=O\left(d_{G}(u, v) / 2^{t_{v}}\right) \\
& \left|p_{t_{u}}-q_{t_{u}}\right|=1-\lambda_{u} \leq \chi=O\left(d_{G}(u, v) / 2^{t_{u}}\right)
\end{aligned}
$$

- $\boldsymbol{t}_{\boldsymbol{u}}<\boldsymbol{t}_{\boldsymbol{v}}-1$ : By the definition of $t_{v}$ and $t_{u}, 2 d_{G}(v, u) \geq$ $2\left(d_{G}(v, V \backslash X)-d_{G}(u, V \backslash X)\right) \geq 2^{t_{v}}-2^{t_{u}+1} \geq 2^{t_{v}-1}$. In particular, for every $t \leq t_{v}+1$,
$\left|p_{t}-q_{t}\right| \leq 1 \leq \frac{2 d_{G}(u, v)}{2^{t_{v}-1}}=O\left(\frac{d_{G}(u, v)}{2^{t}}\right)$.

### 5.2 Bounding the Contraction: Proof of

## Lemma 5.2

Recall that we want to prove that for any pair $u, v$ of vertices, the embedding has a large contribution between them. A natural proof idea is to show that vertices $u, v$ would eventually be separated by the recursive procedure. When they are separated, either one of $u, v$ is far from the separating path $P$, or they both lie close to the path. In the former case, the distance $d(v, P)$ gives a large contribution to the embedding distance, and in the latter case the distance from one end of the path (the "root") gives a large contribution.

However, there's a catch: the value of the $v$ 's embedding in any single coordinate cannot be more than $v$ 's distance to the boundary, and this causes problems. Indeed, if $u, v$ fall very close to the path $P$ at some step of the algorithm, they must get most of their contribution at this level, since future levels will not give much contribution. How can we do it, without assigning large values? This is where we use the sawtooth function: it gives a good contribution between points without assigning any vertex too large a value in any coordinate.

Formally, to bound the contraction and prove Lemma 5.2, for nodes $u, v$ we need to show that there exists a coordinate $j$ such that $\mathbb{E}_{\alpha, \beta}\left[\left|f_{j}(v)-f_{j}(u)\right|\right]=\Omega\left(d_{G}(u, v)\right)$. For brevity, define

$$
\begin{equation*}
\Delta_{u v}:=d_{G}(u, v) \tag{3}
\end{equation*}
$$

Fix $c=12$. Let $i$ be the minimal index such that there exists $X \in X_{i}$ with $u, v \in X$, and at least one of the following holds:
(1) $\min \left\{d_{X}\left(v, P_{X}\right), d_{X}\left(u, P_{X}\right)\right\} \leq \Delta_{u v} / c$ (i.e., we choose a path close to $\{v, u\})$.
(2) $v$ and $u$ are in different components of $X \backslash P_{X}$.

Note that such an index $i$ indeed exists: if $v$ and $u$ are separated by the SPD then condition (2) holds. The only other possibility that $v$ and $u$ are never separated is when at least one of them lies on one of the shortest paths. In such a case, surely condition (1) holds. By the minimality of $i$, for every $X^{\prime} \in X_{i^{\prime}}$ such that $i^{\prime}<i$ and $u, v \in X^{\prime}$, necessarily $\min \left\{d_{X^{\prime}}\left(v, P_{X^{\prime}}\right), d_{X^{\prime}}\left(u, P_{X^{\prime}}\right)\right\}>\Delta_{u v} / c$. Therefore, the ball with radius $\Delta_{u v} / c$ around each of $v, u$ is contained in $X$. In particular, $\min \left\{d_{G}(v, V \backslash X), d_{G}(u, V \backslash X)\right\}>\Delta_{u v} / c$.

Suppose first that (2) occurs but not (1). Let $j$ be the coordinate in $f_{X}^{\text {path }}$ created for the connected component of $v$ in $X \backslash P_{X}$. Then

$$
\begin{aligned}
& \left|\left(f_{X}^{\text {path }}\right)_{j}(v)-\left(f_{X}^{\text {path }}\right)_{j}(u)\right| \\
& \quad=\min \left\{d_{X}\left(v, P_{X}\right), 2 d_{G}(v, V \backslash X)\right\}-0 \\
& \quad \geq \min \left\{\frac{\Delta_{u v}}{c}, 2 \frac{\Delta_{u v}}{c}\right\}=\frac{\Delta_{u v}}{c}
\end{aligned}
$$

Next assume that (1) occurs. W.l.o.g., $d_{X}\left(v, P_{X}\right) \leq d_{X}\left(u, P_{X}\right)$, so that $d_{X}\left(v, P_{X}\right) \leq \Delta_{u v} / c$. Suppose first that $d_{X}\left(u, P_{X}\right) \geq 2 \Delta_{u v} / c$. Then in the coordinate $j$ in $f_{X}^{\text {path }}$ created for the connected component of $u$ in $X \backslash P_{X}$, we have

$$
\begin{aligned}
& \left|\left(f_{X}^{\text {path }}\right)_{j}(v)-\left(f_{X}^{\text {path }}\right)_{j}(u)\right| \\
& \geq \quad \mid \min \left\{d_{X}\left(u, P_{X}\right), 2 d_{G}(u, V \backslash X)\right\} \\
& \quad-\min \left\{d_{X}\left(v, P_{X}\right), 2 d_{G}(v, V \backslash X)\right\} \mid \\
& \geq \min \left\{2 \frac{\Delta_{u v}}{c}, 2 \frac{\Delta_{u v}}{c}\right\}-\frac{\Delta_{u v}}{c}=\frac{\Delta_{u v}}{c}
\end{aligned}
$$

(It does not matter whether $v, u$ are in the same connected component or not.) Thus it remains to consider the case $d_{X}\left(u, P_{X}\right)<$ $2 \Delta_{u v} / c$. Let $r$ be the root of $P_{X}$. Let $v^{\prime}$ (resp. $u^{\prime}$ ) be the closest vertex on $P_{X}$ to $v($ resp. $u)$ in $G[X]$. Then by the triangle inequality

$$
d_{X}\left(v^{\prime}, u^{\prime}\right) \geq d_{X}(v, u)-d_{X}\left(v, v^{\prime}\right)-d_{X}\left(u, u^{\prime}\right) \geq \frac{c-3}{c} \Delta_{u v}
$$

In particular,

$$
\begin{align*}
& \left|d_{X}(v, r)-d_{X}(u, r)\right| \\
& \quad \geq\left|d_{X}\left(v^{\prime}, r\right)-d_{X}\left(u^{\prime}, r\right)\right|-d_{X}\left(v, v^{\prime}\right)-d_{X}\left(u, u^{\prime}\right) \\
& \quad \geq \frac{c-6}{c} \Delta_{u v}=\frac{1}{2} \Delta_{u v} \tag{4}
\end{align*}
$$

where we used that $P_{X}$ is a shortest path in $G[X]$ (implying $\left.\left|d_{X}\left(v^{\prime}, r\right)-d_{X}\left(u^{\prime}, r\right)\right|=d_{X}\left(v^{\prime}, u^{\prime}\right)\right)$. See Figure 5 for illustration.

Figure 5: $P_{X}$ is a shortest path with root $r . v$ (resp. $u$ ) is at distance at most $\frac{\Delta_{u v}}{c}$ (resp. $\frac{2 \Delta_{u v}}{c}$ ) from $v^{\prime}$ (resp $u^{\prime}$ ), it's closest vertex on $P_{X}$. By triangle inequality $d_{X}\left(v^{\prime}, u^{\prime}\right) \geq\left(1-\frac{3}{c}\right) \Delta_{u v}$. As $u^{\prime}, v^{\prime}$ lay on the same shortest path starting at $r, \mid d_{X}\left(v^{\prime}, r\right)-$ $d_{X}\left(u^{\prime}, r\right) \mid=d_{X}\left(v^{\prime}, u^{\prime}\right)$. Using the triangle inequality again we conclude $\left|d_{X}(v, r)-d_{X}(u, r)\right| \geq\left|d_{X}\left(v^{\prime}, r\right)-d_{X}\left(u^{\prime}, r\right)\right|-\frac{3}{c} \Delta_{u v} \geq(1-$ $\left.\frac{6}{c}\right) \Delta_{u v}$.

Set $x=d_{X}(v, r)$ and $y=d_{X}(u, r)$. Assume first that $d_{G}(v, V \backslash X) \geq d_{G}(u, V \backslash X)$. In particular, $t_{v} \geq t_{u}$. By the definition of $t_{v}, 2 d_{G}(v, V \backslash X) \leq 2^{t_{v}+1}$. Thus

$$
\begin{equation*}
2^{t_{v}} \geq \frac{\Delta_{u v}}{c}=\Omega\left(\Delta_{u v}\right) \tag{5}
\end{equation*}
$$

Claim 1. Let $t \geq t_{v}$, then there is a constant $\phi$ such that

$$
\mathbb{E}_{\alpha, \beta}\left[\left|g_{t}\left(\beta \cdot x+\alpha \cdot 2^{t+1}\right)-g_{t}\left(\beta \cdot y+\alpha \cdot 2^{t+1}\right)\right|\right] \geq \Delta_{u v} / \phi
$$

Proof. If $|x-y| \leq 2^{t-1}$, then using Property 2 of Lemma 2.1

$$
\begin{gathered}
\mathbb{E}_{\alpha, \beta}\left[\left|g_{t}\left(\beta \cdot x+\alpha \cdot 2^{t+1}\right)-g_{t}\left(\beta \cdot y+\alpha \cdot 2^{t+1}\right)\right|\right] \\
=\quad \Omega(|x-y|) \stackrel{(4)}{=} \Omega\left(\Delta_{u v}\right)
\end{gathered}
$$

Otherwise, using

$$
\begin{gathered}
\mathbb{E}_{\alpha, \beta}\left[\left|g_{t}\left(\beta \cdot x+\alpha \cdot 2^{t+1}\right)-g_{t}\left(\beta \cdot y+\alpha \cdot 2^{t+1}\right)\right|\right] \\
\quad=\quad \Omega\left(2^{t}\right) \stackrel{(5)}{\geq} \Omega\left(\Delta_{u v}\right)
\end{gathered}
$$

Set $S=\max \left\{8 \phi, \frac{8 c}{2}\right\}$. We consider two cases:

- If for some $t \in\{0,1, \ldots, M\},\left|p_{t}-q_{t}\right| \cdot 2^{t}>\frac{\Delta_{u v}}{S}$, then

$$
\begin{aligned}
& \mathbb{E}_{\alpha, \beta}\left[\left|f_{X, t}^{\mathrm{root}}(v)-f_{X, t}^{\mathrm{root}}(u)\right|\right] \\
& =\mathbb{E}_{\alpha, \beta}\left[\left|p_{t} \cdot g_{t}\left(\beta \cdot x+\alpha \cdot 2^{t+1}\right)-q_{t} \cdot g_{t}\left(\beta \cdot y+\alpha \cdot 2^{t+1}\right)\right|\right] \\
& \geq \\
& \geq\left|p_{t} \cdot \mathbb{E}_{\alpha, \beta}\left[g_{t}\left(\beta \cdot x+\alpha \cdot 2^{t+1}\right)\right]\right| \\
& \quad-q_{t} \cdot \mathbb{E}_{\alpha, \beta}\left[g_{t}\left(\beta \cdot y+\alpha \cdot 2^{t+1}\right)\right] \\
& =\left|p_{t}-q_{t}\right| \cdot 2^{t}=\Omega\left(\Delta_{u v}\right)
\end{aligned}
$$

Where the equality follows by Property 1 of Lemma 2.1.

- The other case is that for every $t,\left|p_{t}-q_{t}\right| \cdot 2^{t} \leq \frac{\Delta_{u v}}{S}$. Note that $p_{t_{v}}+p_{t_{v}+1}=\left(1-\lambda_{v}\right)+\lambda_{v}=1$. Let $t \in\left\{t_{v}, t_{v}+1\right\}$ be such that $p_{t} \geq \frac{1}{2}$. Using (5), $q_{t} \geq p_{t}-\frac{\Delta_{u v}}{2^{t v} \cdot S} \geq \frac{1}{2}-\frac{2 c}{2 \Delta_{u v}} \cdot \frac{\Delta_{u v}}{S} \geq \frac{1}{4}$. In particular,

$$
\begin{aligned}
& \mathbb{E}_{\alpha, \beta}\left[\left|f_{X, t}^{\mathrm{root}}(v)-f_{X, t}^{\mathrm{root}}(u)\right|\right] \\
& = \\
& \quad \mathbb{E}_{\alpha, \beta}\left[\left|p_{t} \cdot g_{t}\left(\beta \cdot x+\alpha \cdot 2^{t+1}\right)-q_{t} \cdot g_{t}\left(\beta \cdot y+\alpha \cdot 2^{t+1}\right)\right|\right] \\
& \geq \min \left\{p_{t}, q_{t}\right\} \cdot \mathbb{E}_{\alpha, \beta}\left[\mid g_{t}\left(\beta \cdot x+\alpha \cdot 2^{t+1}\right)\right. \\
& \left.\quad-g_{t}\left(\beta \cdot y+\alpha \cdot 2^{t+1}\right) \mid\right]-\left|p_{t}-q_{t}\right| \cdot 2^{t} \\
& \geq \\
& \geq \frac{1}{4} \cdot \frac{\Delta_{u v}}{\phi}-\frac{\Delta_{u v}}{S}=\Omega\left(\Delta_{u v}\right)
\end{aligned}
$$

where in the first inequality we used Property 1 of Lemma 2.1, and in the second inequality we used Claim 1.
Finally, recall that we assumed $d_{G}(v, V \backslash X) \geq d_{G}(u, V \backslash X)$ for the proof above. The other case $\left(d_{G}(v, V \backslash X)<d_{G}(u, V \backslash X)\right)$ is completely symmetric.

## 6 PROOF OF <br> THE COMPOSITION LEMMA (5.3)

We restate the lemma for convenience:
Lemma 5.3 (Composition Lemma). Let $(X, d)$ be a metric space. Suppose that there are constants $\rho, \tau$ and a function $f: X \rightarrow \mathbb{R}^{s}$, drawn from some probability space such that:
(1) For every $u, v \in X$ and every $j \in[s],\left|f_{j}(v)-f_{j}(u)\right| \leq \rho$. $d(v, u)$.
(2) For every $u, v \in X$, there exists $j \in[s]$ such that $\mathbb{E}\left[\mid f_{j}(v)-\right.$ $\left.f_{j}(u) \mid\right] \geq \frac{1}{\tau} \cdot d(v, u)$.

Ittai Abraham, Arnold Filtser, Anupam Gupta, Ofer Neiman
(3) For every $v \in X$, there is a subset of indices $I_{v} \subseteq[s]$ of size $\left|I_{v}\right| \leq k$, such that for every $j \notin I_{v}, f_{j}(v)=0$. In other words, for every $v \in X, f(v)$ has support of size at most $k$.
Then, for every $p \geq 1$, there is an embedding of $(X, d)$ into $\ell_{p}$ with distortion $O\left(k^{1 / p}\right)$. Moreover, if there is an efficient algorithm for sampling such an $f$, then there is a randomized algorithm that constructs the embedding efficiently (in expectation).

Proof. Fix $n=|X|$, and set $m=48 \rho \tau \cdot \ln n$. Let $f^{(1)}, f^{(2)}, \ldots, f^{(m)}: X \rightarrow \mathbb{R}^{s}$ be functions chosen i.i.d according to the given distribution. Set $g=m^{-1 / p} \bigoplus_{i=1}^{m} f^{(i)}$. We argue that with high probability, $g$ has distortion $O\left(k^{1 / p}\right)$ in $\ell_{p}$.

Fix some pair of vertices $v, u \in V$. Set $d(v, u)=\Delta$. The upper bound follows from Property 1 and Property 3 of the lemma:

$$
\begin{aligned}
\|g(v)-g(u)\|_{p}^{p} & =\sum_{i=1}^{m} \sum_{j \in I_{v} \cup I_{u}}\left(m^{-1 / p} \cdot\left|f_{j}^{(i)}(v)-f_{j}^{(i)}(u)\right|\right)^{p} \\
& \leq \sum_{i=1}^{m} \sum_{j \in I_{v} \cup I_{u}} \frac{1}{m} \cdot(\rho \cdot \Delta)^{p} \leq 2 k \cdot(\rho \cdot \Delta)^{p}
\end{aligned}
$$

thus $\|g(v)-g(u)\|_{p} \leq O\left(k^{1 / p} \cdot \Delta\right)$.
Next, for the contraction bound, let $j$ be the index of Property 2 w.r.t $v, u$. Set $\mathcal{F}=\left\{f:\left|f_{j}(v)-f_{j}(u)\right| \geq \Delta / 2 \tau\right\}$ to be the event that we draw a function with significant contribution to $v, u$. Then using Property 1 and Property 2,

$$
\begin{aligned}
\frac{\Delta}{\tau} & \leq \mathbb{E}\left[\left|f_{j}(v)-f_{j}(u)\right|\right] \\
& \leq \operatorname{Pr}[\overline{\mathcal{F}}] \cdot \frac{\Delta}{2 \tau}+\operatorname{Pr}[\mathcal{F}] \cdot \rho \Delta \leq \frac{\Delta}{2 \tau}+\operatorname{Pr}[\mathcal{F}] \cdot \rho \Delta
\end{aligned}
$$

which implies that $\operatorname{Pr}[\mathcal{F}] \geq \frac{1}{2 \rho \tau}$. Let $Q_{u, v}^{(i)}$ be an indicator random variable for the event $f^{(i)} \in \mathcal{F}$, and set $Q_{u, v}=\sum_{i=1}^{m} Q_{u, v}^{(i)}$. By linearity of expectation, $\mathbb{E}\left[Q_{u, v}\right] \geq \frac{m}{2 \rho \tau}=24 \cdot \ln n$. By a Chernoff bound

$$
\begin{aligned}
\operatorname{Pr}\left[Q_{u, v} \leq 12 \cdot \ln n\right] & \leq \operatorname{Pr}\left[Q_{u, v} \leq \frac{1}{2} \cdot \mathbb{E}\left[Q_{u, v}\right]\right] \\
& \leq \exp \left(-\frac{1}{8} \mathbb{E}\left[Q_{u, v}\right]\right) \\
& \leq \exp (-3 \ln n)=n^{-3}
\end{aligned}
$$

By taking a union bound over the $\binom{n}{2}$ pairs, with probability at least $1-\frac{1}{n}$, for every $u, v \in V, Q_{u, v}>12 \ln n=\Omega(m)$. (Recall that both $\rho, \tau$ are universal constants.) If this event indeed occurs, then the contraction is indeed bounded:

$$
\begin{aligned}
\|g(v)-g(u)\|_{p}^{p} & \geq \sum_{i=1}^{m}\left(m^{-1 / p} \cdot\left|f_{j}^{(i)}(v)-f_{j}^{(i)}(u)\right|^{p}\right. \\
& \geq \frac{1}{m} \sum_{i: Q_{u, v}^{(i)}=1}\left|f_{j}^{(i)}(v)-f_{j}^{(i)}(u)\right|^{p} \\
& \geq \frac{Q_{u, v}}{m} \cdot\left(\frac{\Delta}{2 \rho \tau}\right)^{p}=\Omega\left(\left(\frac{\Delta}{2 \rho \tau}\right)^{p}\right)
\end{aligned}
$$

In particular, for every $u, v,\|g(v)-g(u)\|_{p} \geq \Omega(\Delta)$.

Figure 6: $\alpha$ is going from 0 to $2^{t+1} . z \leq 2^{t}$. In each of the figures the leftmost red point represents $\alpha$ while the rightmost red point represents $z+\alpha$. Each of the middle figures represent a moment when $g_{t}(z+\alpha)-g_{t}(z)$ changes its derivative.

## 7 PROOF OF THE SAWTOOTH LEMMA (2.1)

We restate Lemma 2.1 for convenience:

Lemma 2.1 (Sawtooth Lemma). Let $x, y \in \mathbb{R}_{+}$. Let $\alpha \in[0,1]$, $\beta \in[0,4]$ be drawn uniformly and independently. The following properties hold:
(1) $\mathbb{E}_{\alpha, \beta}\left[g_{t}\left(\beta x+\alpha \cdot 2^{t+1}\right)\right]=2^{t-1}$.
(2) If $|x-y| \leq 2^{t-1}$, then

$$
\mathbb{E}_{\alpha, \beta}\left[\left|g_{t}\left(\beta x+\alpha \cdot 2^{t+1}\right)-g_{t}\left(\beta y+\alpha \cdot 2^{t+1}\right)\right|\right]=\Omega(|x-y|)
$$

(3) If $|x-y|>2^{t-1}$, then

$$
\mathbb{E}_{\alpha, \beta}\left[\left|g_{t}\left(\beta x+\alpha \cdot 2^{t+1}\right)-g_{t}\left(\beta y+\alpha \cdot 2^{t+1}\right)\right|\right]=\Omega\left(2^{t}\right)
$$

Property 1 is straightforward, as by Observation $1 g_{t}$ is periodic with period length $2^{t+1}$. Indeed, for every fixed $\beta$, $\mathbb{E}_{\alpha}\left[g_{t}\left(\beta x+\alpha \cdot 2^{t+1}\right)\right]=\mathbb{E}_{\alpha}\left[g_{t}\left(\alpha \cdot 2^{t+1}\right)\right]=2^{t-1}$. The following claim will be useful in the proofs of Property 2 and Property 3.

$$
\text { Claim } \quad \text { 2. For } \quad z \quad \in \quad\left[0,2^{t+1}\right]
$$

$\mathbb{E}_{\alpha \in[0,1]}\left[\left|g_{t}\left(z+\alpha \cdot 2^{t+1}\right)-g_{t}\left(\alpha \cdot 2^{t+1}\right)\right|\right]=\frac{\left(2^{t+1}-z\right) z}{2^{t+1}}$.

Proof. Set $(*)=\mathbb{E}_{\alpha \in[0,1]}\left[\left|g_{t}\left(z+\alpha \cdot 2^{t+1}\right)-g_{t}\left(\alpha \cdot 2^{t+1}\right)\right|\right]$. By substituting the variable of integration, $(*)=\frac{1}{2^{t+1}}$. $\int_{0}^{2^{t+1}}\left|g_{t}(z+\alpha)-g_{t}(\alpha)\right| d \alpha$. First assume that $z \leq 2^{t}$, then there are 5 "phase changes" in $\left|g_{t}(z+\alpha)-g_{t}(\alpha)\right|$ from 0 to $2^{t+1}$, at $2^{t}-z, 2^{t}-\frac{z}{2}, 2^{t}, 2^{t+1}-z, 2^{t+1}-\frac{z}{2}$. (see Figure 6 for illustration).

We calculate

$$
\begin{aligned}
2^{t+1} \cdot(*)= & \int_{0}^{2^{t}-z} z d \alpha+\int_{0}^{\frac{z}{2}}(z-2 \alpha) d \alpha+\int_{0}^{\frac{z}{2}} 2 \alpha d \alpha \\
& +\int_{0}^{2^{t}-z} z d \alpha+\int_{0}^{\frac{z}{2}}(z-2 \alpha) d \alpha+\int_{0}^{\frac{z}{2}} 2 \alpha d \alpha \\
= & 2 \cdot \int_{0}^{2^{t}-z} z d \alpha+2 \cdot \int_{0}^{\frac{z}{2}} z d \alpha=\left(2^{t+1}-z\right) z
\end{aligned}
$$

For $z>2^{t}$, set $w=2^{t+1}-z$. Then using that $g^{t}$ is periodic,

$$
\begin{aligned}
& \mathbb{E}_{\alpha \in[0,1]}\left[\left|g_{t}\left(w+\alpha \cdot 2^{t+1}\right)-g_{t}\left(\alpha \cdot 2^{t+1}\right)\right|\right] \\
& \quad=\mathbb{E}_{\alpha \in[0,1]}\left[\left|g_{t}\left(w+z+\alpha \cdot 2^{t+1}\right)-g_{t}\left(z+\alpha \cdot 2^{t+1}\right)\right|\right] \\
& \quad=\mathbb{E}_{\alpha \in[0,1]}\left[\left|g_{t}\left(2^{t+1}+\alpha \cdot 2^{t+1}\right)-g_{t}\left(z+\alpha \cdot 2^{t+1}\right)\right|\right] \\
& \quad=\mathbb{E}_{\alpha \in[0,1]}\left[\left|g_{t}\left(z+\alpha \cdot 2^{t+1}\right)-g_{t}\left(\alpha \cdot 2^{t+1}\right)\right|\right] .
\end{aligned}
$$

Hence by the first case, $(*)=\frac{\left(2^{t+1}-w\right) w}{2^{t+1}}=\frac{\left(2^{t+1}-z\right) z}{2^{t+1}}$.

For the proofs of Property 2 and Property 3 assume w.l.o.g $x>y$. Set $z=x-y$, and $(*) \quad=\quad \mathbb{E}_{\alpha, \beta}\left[\left|g_{t}\left(\beta x+\alpha \cdot 2^{t+1}\right)-g_{t}\left(\beta y+\alpha \cdot 2^{t+1}\right)\right|\right]$. As $g_{t}$ is a periodic function, we have that $(*)=$ $\mathbb{E}_{\beta}\left[\mathbb{E}_{\alpha}\left[\left|g_{t}\left(\beta z+\alpha \cdot 2^{t+1}\right)-g_{t}\left(\alpha \cdot 2^{t+1}\right)\right|\right]\right]$.

Proof of Property 2. Using Claim 2, we have

$$
\begin{aligned}
& (*)=\mathbb{E}_{\beta}\left[\frac{\left(2^{t+1}-\beta z\right) \beta z}{2^{t+1}}\right]=\frac{1}{2^{t+1}} \cdot \frac{1}{4} \cdot\left(\frac{2^{t+1} z}{2} \beta^{2}-\left.\frac{z^{2}}{3} \cdot \beta^{3}\right|_{0} ^{4}\right) \\
& \quad=\frac{1}{4} \cdot\left(\frac{16}{2} \cdot z-\frac{z^{2}}{2^{t+1}} \cdot \frac{2^{6}}{3}\right) \geq \frac{1}{4} \cdot\left(8-\frac{64}{3 \cdot 4}\right) \cdot z=\frac{2}{3} \cdot|x-y|
\end{aligned}
$$

where in the inequality we used that $z \leq 2^{t-1}$.

Proof of Property 3. As $g_{t}$ is periodic function, Claim 2 implies that for every $w \geq 0$ it holds that $\mathbb{E}_{\alpha}\left[\left|g_{t}\left(w+\alpha \cdot 2^{t+1}\right)-g_{t}\left(\alpha \cdot 2^{t+1}\right)\right|\right] \quad=$ $\frac{\left(2^{t+1}-\left(w \bmod 2^{t+1}\right)\right)\left(w \bmod 2^{t+1}\right)}{2^{t+1}}$. Let $a \in[0,4]$ such that $a \cdot z=2^{t+1}$

Ittai Abraham, Arnold Filtser, Anupam Gupta, Ofer Neiman

Figure 7: The first 3 diamond graphs. $\{s, t\}$ is the level 0 diagonal, $\{u, v\}$ is the level 1 diagonal, $\left\{a_{1}, a_{2}\right\},\left\{b_{1}, b_{2}\right\},\left\{c_{1}, c_{2}\right\}$, $\left\{d_{1}, d_{2}\right\}$ are the level 2 diagonals. $E_{0}=\{\{s, t\}\}, E_{1}=$ $\{\{s, u\},\{t, u\},\{t, v\},\{s, v\}\}$.

Define $x_{1}=b-a, y_{1}=a-d$ and $x_{2}=b-c, y_{2}=c-d$. We get

$$
\begin{gathered}
\|b-d\|_{p}^{p}+\|b-2 a+d\|_{p}^{p} \leq 2^{p-1}\left(\|a-b\|_{p}^{p}+\|d-a\|_{p}^{p}\right) . \\
\|b-d\|_{p}^{p}+\|b-2 c+d\|_{p}^{p} \leq 2^{p-1}\left(\|b-c\|_{p}^{p}+\|c-d\|_{p}^{p}\right) .
\end{gathered}
$$

By summing up and dividing by 2 ,

$$
\begin{aligned}
& \|b-d\|_{p}^{p}+\frac{\|b-2 a+d\|_{p}^{p}+\|b-2 c+d\|_{p}^{p}}{2} \\
& \quad \leq \quad 2^{p-2}\left(\|a-b\|_{p}^{p}+\|b-c\|_{p}^{p}+\|c-d\|_{p}^{p}+\|d-a\|_{p}^{p}\right) .
\end{aligned}
$$

The claim now follows by convexity.

Fix some $p \geq 2$, and embedding $f: \mathcal{D}_{k} \rightarrow \ell_{p}$. We will assume w.l.o.g that $f$ is non-contractive, and denote by $\rho$ its expansion, i.e. distortion. Set $\alpha_{0}=\frac{1}{2^{k(p-2)}}$ and for $i>0, \alpha_{i}=\frac{1}{2^{(k-i+1)(p-2)}}$. Note that for $i \geq 1, \alpha_{i} \cdot 2^{p-2}=\alpha_{i+1}$. Our proof will be based on the following Poincaré-type inequality

Claim 4 (Diamond graph $\ell_{p}$ Poincaré-type inequality).

$$
\begin{align*}
& \sum_{i=0}^{k} \alpha_{i} \cdot \sum_{\{x, y\} \in D_{i}}\|f(x)-f(y)\|_{p}^{p} \\
& \quad \leq \quad \alpha_{k+1} \cdot \sum_{\{x, y\} \in E_{k}}\|f(x)-f(y)\|_{p}^{p} \tag{7}
\end{align*}
$$

Proof. For edge $\{x, y\} \in E_{i-1}$, denote by $\left\{x^{\prime}, y^{\prime}\right\} \in D_{i}$ the diagonal created by it. We have

$$
\begin{aligned}
& \quad \sum_{\{x, y\} \in D_{i}}\|f(x)-f(y)\|_{p}^{p}+\sum_{\{x, y\} \in E_{i-1}}\|f(x)-f(y)\|_{p}^{p} \\
& =\sum_{\{x, y\} \in E_{i-1}}\left(\|f(x)-f(y)\|_{p}^{p}+\left\|f\left(x^{\prime}\right)-f\left(y^{\prime}\right)\right\|_{p}^{p}\right) \\
& \stackrel{(6)}{\leq} 2^{p-2} \cdot\left(\sum _ { \{ x , y \} \in E _ { i - 1 } } \left(\left\|f(x)-f\left(x^{\prime}\right)\right\|_{p}^{p}+\left\|f\left(x^{\prime}\right)-f(y)\right\|_{p}^{p}\right.\right. \\
& \left.\left.\quad+\left\|f(y)-f\left(y^{\prime}\right)\right\|_{p}^{p}+\left\|f\left(y^{\prime}\right)-f(x)\right\|_{p}^{p}\right)\right) \\
& =2^{p-2} \cdot \sum_{\{x, y\} \in E_{i}}\|f(x)-f(y)\|_{2}^{2} .
\end{aligned}
$$

Summing over $1 \leq i \leq k$ 's, with appropriate scaling,

$$
\begin{aligned}
\sum_{i=1}^{k} \alpha_{i} \cdot & \left(\sum_{\{x, y\} \in D_{i}}\|f(x)-f(y)\|_{p}^{p}\right. \\
& \left.+\sum_{\{x, y\} \in E_{i-1}}\|f(x)-f(y)\|_{p}^{p}\right) \\
\leq & \sum_{i=1}^{k} \alpha_{i} \cdot 2^{p-2} \cdot \sum_{\{x, y\} \in E_{i}}\|f(x)-f(y)\|_{p}^{p} \\
= & \sum_{i=1}^{k} \alpha_{i+1} \cdot \sum_{\{x, y\} \in E_{i}}\|f(x)-f(y)\|_{p}^{p}
\end{aligned}
$$

Hence

$$
\begin{aligned}
& \sum_{i=1}^{k} \alpha_{i} \cdot \sum_{\{x, y\} \in D_{i}}\|f(x)-f(y)\|_{p}^{p} \\
& \quad+\alpha_{1} \cdot \sum_{\{x, y\} \in E_{0}}\|f(x)-f(y)\|_{p}^{p} \\
& \leq \alpha_{k+1} \cdot \sum_{\{x, y\} \in E_{k}}\|f(x)-f(y)\|_{p}^{p}
\end{aligned}
$$

As $E_{0}=D_{0}$ and $\alpha_{0}=\alpha_{1}$, the claim follows.

Next, we calculate

$$
\begin{align*}
& \sum_{i=0}^{k} \alpha_{i} \cdot \sum_{\{x, y\} \in D_{i}} d(x, y)^{p} \\
& \quad=\alpha_{0} \cdot\left(2^{k}\right)^{p}+\sum_{i=1}^{k}\left|D_{i}\right| \cdot \alpha_{i} \cdot\left(2^{k-i+1}\right)^{p} \\
& \quad=2^{2 k}+\sum_{i=1}^{k} 4^{i-1} \cdot\left(2^{k-i+1}\right)^{2}=(k+1) \cdot 4^{k} . \tag{8}
\end{align*}
$$

Recall that $f$ is non-contractive and has expansion $\rho$. Consequently,

$$
\begin{aligned}
(k+1) \cdot 4^{k} & \stackrel{(8)}{=} \sum_{i=0}^{k} \alpha_{i} \cdot \sum_{\{x, y\} \in D_{i}} d(x, y)^{p} \\
& \leq \sum_{i=0}^{k} \alpha_{i} \cdot \sum_{\{x, y\} \in D_{i}}\|f(x)-f(y)\|_{p}^{p} \\
& \stackrel{(7)}{\leq} \alpha_{k+1} \cdot \sum_{\{x, y\} \in E_{k}}\|f(x)-f(y)\|_{p}^{p} \\
& \leq \alpha_{k+1} \cdot \sum_{\{x, y\} \in E_{k}}(\rho \cdot d(x, y))^{p} \\
& =\alpha_{k+1} \cdot(\rho)^{p} \cdot\left|E_{k}\right| .
\end{aligned}
$$

We conclude

$$
\rho \geq\left(\frac{4^{k}}{\left|E_{k}\right|} \cdot \frac{k+1}{\alpha_{k+1}}\right)^{1 / p}=\left(\frac{k+1}{2^{p-2}}\right)^{1 / p}=\Omega\left(k^{1 / p}\right) .
$$

## 9 CONCLUSIONS

In this paper we introduced the notion of shortest path decompositions with low depth. We showed how these can be used to give embeddings into $\ell_{p}$ spaces. Our techniques give optimal embeddings of bounded pathwidth graphs into $\ell_{2}$, and also new embeddings for graphs with bounded treewidth, as well as planar and excluded-minor families of graphs. Our embedding into $\ell_{p}$ admits a tight lower bound for fixed $p>1$. We hope that our techniques will be useful for other embedding results.

Our work raises several open questions. While our embeddings are tight for fixed $p>1$, can we improve the bounds for $\ell_{1}$ embedding of bounded pathwidth graphs? Can we give better results for the SPDdepth of $H$-minor-free graphs? Our approach gives a $O(\sqrt{\log n})$-distortion embedding of planar graphs into $\ell_{1}$, which is quite different from the previous known results via padded decompositions: can these ideas be used to make progress towards the planar graph embedding conjecture?

[^1]:    ${ }^{1}$ In fact, we use different dimensions for each connected components.

[^2]:    ${ }^{2}$ i.e. for every $X \in X_{i}, X \subseteq V$, and for every different subsets $X, X^{\prime} \in X_{i}, X \cap X^{\prime}=$ $\emptyset$.
